

a. Statistical power

b. Type M error (exaggeration ratio)

c. Type S error

Violins show the distribution of all 5,740 effect-size estimates (primary-study level) or all 48 meta-analysis models (meta-analysis level).

Points are individual estimates, drawn smaller and fainter at the primary-study level because there are 5,740 of them against 48.

Horizontal bars show model-based summaries for power, Type M error and primary-study-level Type S error. For meta-analysis-level Type S

error, horizontal bars show raw medians and intervals show interquartile ranges; the corresponding model-based estimates are retained in

Table S1 for comparability. Type S error is bounded above at 0.5, the value taken when the assumed effect is zero, and is not shown on a

logarithmic scale because values can reach or approach zero. Type M error is unbounded as the assumed effect approaches zero.
